

CLAIMS

1 1. An improved cap for sealed joints between adjacent  
2 blocks, comprising:

3 a) a flexible body member, comprising a first cap portion  
4 and a leg portion;

5 b) a plurality of ridges positioned on an underside cap  
6 portion, having a plurality of channels there between, the ridges  
7 further defining an increased area on the underside of the cap  
8 for sealant to adhere to;

9 c) the leg portion insertable into fluidized sealant  
10 material within the joint between the adjacent blocks, to a depth  
11 so that the underside of the cap portion imbeds into the sealant  
12 material for providing a sealed connection between the underside  
13 of the cap and the fluidized sealant material residing in the  
14 joint and on an upper surfaces of the adjacent blocks.

15 2. The improved cap in claim 1, wherein the cap is  
16 constructed of material such as lead or other type of material  
17 having similar characteristics.

18 3. The improved cap in claim 1, wherein the leg member  
19 further comprises a pointed end having shoulder members for  
20 adhering within the sealant material.

21 4. The improved cap in claim 1, wherein the plurality of  
22 ridges and channels on the underside of the cap portion define  
23 a means for adhering to the fluidized sealant and the upper  
24 portion of the adjacent blocks for withstanding movement and  
25 preventing damage to the sealed joint.

26 5. The improved cap in claim 1, wherein the cap may be  
27 positioned to seal a joint between horizontal and vertical  
28 surfaces.

1           6.    An improved cap for sealed joints between adjacent  
2 building members, such as concrete blocks, comprising:

3           a) a flexible body member, comprising a first cap portion  
4 having a first smooth upper surface, an undersurface, and a leg  
5 portion extending down from the undersurface;

6           b) a plurality of ridges positioned on the undersurface of  
7 the cap portion, defining a plurality of channels there between,  
8 the plurality of ridges and channels increasing the surface area  
9 on the underside of the cap by approximately 50% for the sealant  
10 to adhere to, thus strengthening the seal between the cap and the  
11 concrete or stone blocks the cap is set upon;

12           c) fluidized sealant material placed within the joint  
13 between the adjacent building members;

14           d) the leg portion insertable into the fluidized sealant  
15 material to a depth so that the underside of the cap portion  
16 imbeds into the sealant material for providing a sealed  
17 connection between the underside of the cap and the fluidized  
18 sealant material residing in the joint and on surfaces of the  
19 adjacent blocks.

1           7.    The improved cap in claim 6, wherein the sealant  
2 material comprises caulking or the like material.

1           8.    The improved cap in claim 6, wherein the underside of  
2 the cap increases the area for the sealant to adhere to,  
3 improving the bond between the cap and the stones and  
4 strengthening the seal between the two.

1           9.    The improved cap in claim 6, wherein the cap comprises  
2 a continuous strip of flexible material extending uninterrupted  
3 over the joint which needs to be sealed.

1           10. A method of sealing a joint between adjacent building  
2 blocks, comprising the following steps:

3           a) filling the joint with a fluidized sealing material such  
4 as caulking;

5           b) providing a cap, the cap having a cap portion and a  
6 downward depending leg portion;

7           c) inserting the leg portion down in to the fluidized  
8 sealing material to a point that an underside of the cap portion  
9 makes sealing contact with the fluidized sealing material;

10          d) providing a plurality of ridges, which define a plurality  
11 of channels there between on an underside of the cap portion, the  
12 ridges and channels increasing the area on the underside of the  
13 cap for the sealant to adhere to, improving the bond between the  
14 cap and the stones and strengthening the seal between the two.

15          11. The method in claim 10, further comprising the step of  
16 removing the excess sealant material from around the cap before  
17 the sealant completely sets.

18          12. The method in claim 10, the insertion of the leg  
19 portion of the cap down into the sealing material decreases the  
20 size of a joint by one half therefore defining two joint spaces,  
21 rather than a single space.  
22  
23  
24
